Keywords: CO_2 capture Amine VLE Partial pressure

ABSTRACT

Amine volatility is an important parameter to be considered when used as a solvent for CO_2 capture. If the volatility is high, there is a need to inject the solvent so as to compensate the loss consequently the cost of the process increases. In this work CO_2 solubility and amine volatility in loaded and non-loaded aqueous 30 wt% MEA (monoethanolamine), 10, 30 and 50 wt% TMEDA (N,N',N'-tetramethylethylene diamine) were studied in the range of temperature (293 to 353 K) and pressure (2 Pa–400 kPa). Volatility measurements, in terms of partial pressures, were performed using a static apparatus with on-line analysis of the gas phase by GC to determine CO_2 , water and amine partial pressures above the solution. The dissolved CO_2 in the liquid was determined by titration. The experimental data of the system (water + MEA), (water + TMEDA), and (water+MEA+ CO_2) are in a good agreement with literature data. No data for comparison were found for the system (water + TMEDA + CO_2). Experimental partial pressures of the amines (P_{MEA} and P_{TMEDA}) were correlated using the empirical models developed by (Xu, 2011). Both models represent well the experimental data.

1. Introduction

Post-combustion absorption-stripping using aqueous amine is the leading process for CO_2 capture. Aqueous monoethanolamine (MEA) is considered to be the reference solvent for this application. This is the case of the pilot plant inaugurated in 2006 in Elsam (Denmark).

However several alternative solvents among which tertiary class of amine, compound with several function of amine, ionic liquids ... are studied to assess their CO2 absorption load, degradation and evaporation ratio.

The use of a solvent with high volatility, in addition to the environmental impact of the solvent vapors, will increase the cost of the $\rm CO_2$ capture process because of the need to reload the solvent to optimize the reaction (Nguyen, 2013). For these reasons, it is important to determine the volatility (vapor pressures) of solvents with the aim of developing thermodynamic model to optimize the process performance.

Several authors studied vapor-liquid equilibrium of aqueous amine but very few determined the mole fraction of the amine in the vapor

phase (volatility). (McLees, 2006) measured the volatility of MEA between 308 and 343 K in the binary system (water + MEA) as well as in blends with piperazine (PZ) as a promoter. The data was obtained using infrared spectroscopy (FTIR). (Nguyen, 2013) studied 20 aqueous alkanolamines, in the temperature range between 313 and 343 K using FTIR analytical method. Recently, (Du et al., 2017) measured the volatility (expressed in Henry's law constant) of 24 novel amines with different molecular structure (tertiary amines, hindered amines, ether amines and pyridine derivative) at 313 K using FTIR technique.

This work investigates the volatilities of two aqueous amine solvents: monoethanolamine (MEA) and N,N',N'-tetramethylethylene diamine (TMEDA) at different temperatures (293, 313, 333 and 353 K). The compositions of the systems are 30 wt% of MEA in water and 10, 30 and 50 wt% of TMEDA in water. These solutions were also studied at different $\rm CO_2$ loading. The partial pressure of amine, water and $\rm CO_2$ were obtained using a static apparatus with on-line GC analysis of the vapor phase. The loading of $\rm CO_2$ was determined by volumetric titration (Mahi et al., 2019).

In a second step, the volatilities of these amines, in terms of partial pressures, were correlated using two empirical models developed by Xu (2011). The models represent well our experimental data.

As mentioned previously, the system (MEA+ H_2O+CO_2) has already been studied in the literature using different analytical methods. Its study was undertaken in the present work in order to validate our analytical GC method.

2. Experimental section

2.1. Materials

The chemicals, monoethanolamine (MEA), N,N,N',N'-Tetramethylethylene diamine (TMEDA) and hydrochloric acid (HCl, 5 N used for volumetric titration of CO₂) were purchased from Sigma-Aldrich and were used without further purification. CO₂ was supplied by Air Liquide with mole fraction purity >0.999, Table 1. High purity deionized water (conductivity $=18~\text{M}\Omega\text{-cm}$) was used. A digital balance (Mettler-Toledo AG204) having an accuracy of 0.0001 g was used.

2.2. Experimental procedures

The description of the apparatus and the experimental procedure can be found in our earlier work (Mahi et al., 2019). The prominent information is given here. The apparatus is composed of a glass equilibrium

cell with a double envelope for thermoregulated water circulation. The sample is stirred (2000 rpm) by a self-aspirating hollow stirrer. The injected CO_2 and the total pressure of the solution are controlled by an absolute pressure gage (relative uncertainty of 0.5%). The temperature of the solution is monitored by a thermocouple (absolute uncertainty of \pm 0.1 K).

The gaseous phase is analyzed by a gas chromatograph GC Agilent 7890B equipped with two detectors: TCD (for water and CO_2 analysis) and FID (for MEA and TMEDA analysis). For a good separation, two capillary columns were mounted in parallel at the outlet of the injector. In Table 2 are reported the analytical conditions.

At the beginning of the experimental procedure, the degassed solution is introduced into the autoclave previously maintained at high vacuum and heated (for cleaning) along with the gas transfer line, Fig. 1. A first injection of CO2 is then carried out.

Once the equilibrium of the solution amine + water/CO2 is obtained and as long as the total pressure is under the atmospheric pressure, helium gas (slightly above 1 bar) is introduced into the cell. This operation allows the transport of the vapor phase for analysis towards the gas chromatograph using the peristaltic pump and via the sampling loop, Fig. 1. The next increment of CO2 is injected after purging the vapor phase of the cell.

The calibration of the GC is carried out in the same way as the partial pressure determinations described above. The pure degassed amine or water is introduced into the cell and stirred. A chromatogram with a peak corresponding to the amine/water is obtained. The area of the peak is function of the vapor pressure of the pure compound at the studied temperature. The vapor pressures of pure MEA is from (Belabbaci et al., 2009), whereas for pure TMEDA and water, we used (Bouzina et al., 2015) data. Several temperatures are studied to obtain enough points to plot the calibration curve which is a straight line: P/Pa = f (peak area). As for CO_2 calibration, various CO_2 -helium standard mixtures were prepared, introduced in the cell, sampled and analyzed using the system in Fig. 1. The total pressure of the mixture (fixed in the vicinity of the atmospheric pressure) is taken into account to deduce the partial pressure of CO_2 .

The determinations of the partial pressures, P_b of the amines, water and CO_2 were repeated several times until the relative standard deviation, RSD, is less than 2%, Eqs. (1) and (2):

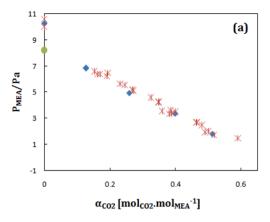

$$Pi = a_i * A_i \tag{1}$$

Where

 a_i is the slope of the calibration curve A_i is the peak area

$$RSD = 100 * \frac{\sigma}{P_{i}^{mean}}$$
 (2)

 σ , is the standard deviation of *Pi*. The relative uncertainty, u_r , of the *Pi* is estimated to be 2 times the RSD, 4%.

3. Results and discussion

3.1. Vapor-liquid equilibria of water + MEA or TMEDA

The VLE of the binary systems were studied at different temperatures and for different compositions (30, 40 wt% MEA and 10, 30, 50 wt% TMEDA), Tables 3 and 4.

The partial pressures of MEA and TMEDA are not determined in the literature but only the total pressures of the aqueous solutions. For the sake of comparison, we calculated the total pressure of the binary system

which is the sum of the 2 experimental partial pressures ($P_{amine} + P_{water}$). We assumed that the non-ideality of the vapor phase ($y_i = P_i/P_b$) could be neglected. In Fig. 2 we plotted the total vapor pressures of water + 30 wt% MEA from this work and those reported by Belabbaci et al. (2009) obtained by a direct method, (Hilliard, 2008) and (McLees, 2006). A very good agreement is observed with our experimental data.

In the same way, experimental vapor pressures of the system water + TMEDA (10, 30 and 50 wt%) from chromatographic analysis show good agreement with (Bouzina et al., 2015) data, Fig. 3. The authors determined the vapor pressures of the solution by a direct method using

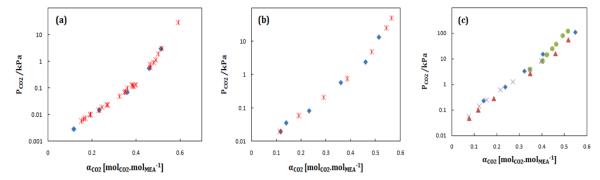

Fig. 7. Partial pressures of CO_2 in (H_2O - 30 wt% MEA- CO_2) mixtures at 313 (a), 333 K (b) and 353 K (c). Comparison with literature data: this work, (Hilliard, 2008), (Jou et al., 1995); •, (Shen and Li, 1992); ×, (Aronu et al., 2011).

 $u\left(\mathbf{x_{i}}\right)=\pm\ 0.0001$; $u(T)=\pm\ 0.1$ K ; $u_{r}\left(\mathbf{P_{i}}\right)=4\%$; $u_{r}\left(\alpha\right)=2\%$.

a pressure sensor.

3.2. Vapor-liquid equilibria of (water+MEA+ CO_2) and (water+ TMEDA+ CO_2)

Partial pressures of water, MEA, TMEDA and CO_2 were determined at 293, 313, 333 and 353 K. The CO_2 loading, α , determined by titration is as follows, Eq. (3):

$$\alpha = \frac{\text{mol of } CO_2 \text{ in the liquid phase}}{\text{mol of amine}}$$
(3)

3.3. Vapor-liquid equilibria of (water + 30 wt% MEA + CO₂)

The experimental results, (T, partial pressures P_i of water, or MEA, or CO_2 along with α) are reported in Table 5. The gradual decrease of the partial pressure of amine, P_{MEA} , when the CO_2 loading α increases, is shown in Figs. 4 and 5 (a). This behavior is expected because the amine reacts with CO_2 and there is less free amine in the solution as the loading

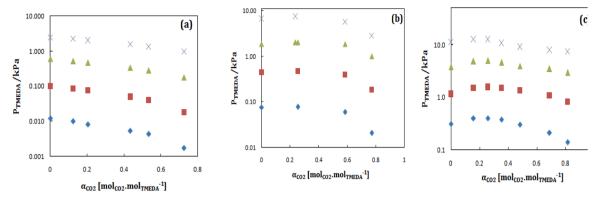

Fig. 8. Partial pressure of TMEDA in (H₂O-TMEDA-CO₂) mixtures. (a): 10 wt%TMEDA; (b), 30 wt% TMEDA; (c), 50 wt% TMEDA at 293; \square , 313;, 333 and \times , 353 K.

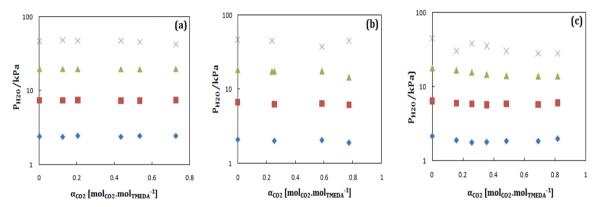

Fig. 9. Partial pressure of H₂O in (H₂O-TMEDA-CO₂) mixtures. (a): 10 wt%TMEDA; (b), 30 wt% TMEDA; (c), 50 wt% TMEDA at , 293; 313, 333 and ×, 353 K.

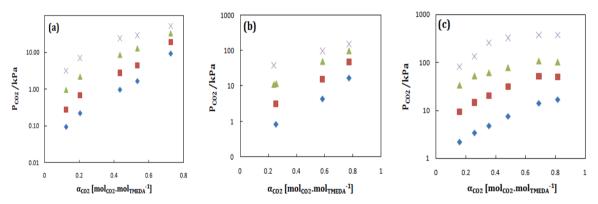

Fig. 10. Partial pressure of CO₂ in (H₂O-TMEDA-CO₂) mixtures. (a): 10 wt%TMEDA; (b), 30 wt% TMEDA; (c), 50 wt% TMEDA at 293, 313; 333 and ×, 353 K.

of CO_2 increases. For a loading equal to $\alpha=0.5$, the chemical absorption of CO_2 by the MEA is at the maximum: all MEA molecules have been consumed to form the carbamate salts, RNHCOO $^-$, practically non-volatile. Consequently P_{MEA} tends to zero.

Having observed a regular decrease in the partial pressure of MEA when alpha increases, we fitted by a straight line our experimental partial pressures, Pexp versus α . From the obtained parameters (slope and intercept of the line), we determined Pcal. In Figs. 4 and 5 (b) we represented the relative deviation between experimental data (from this work and from literature) and Pcal at 313 and 333 K. At 313 K, our data are in a good agreement with (Hilliard, 2008) but at 333 K, there is an offset between the two sets of measurements when the loading (α) is less than 0.4. These deviations must be put into perspective because the partial pressures of MEA are very low (between 1 and 8 Pa at 313 K and between 6 and 42 Pa at 333 K).

Belabbaci et al. (2009) determined experimentally the total vapor pressures of the binary mixture (MEA+eau), P_t , and calculated the vapor composition, y_{MEA}^{cal} , using Barker method (Barker, 1953). From Eq. (4), we deduced the partial pressure of MEA, P_{MEA}^{cal} , assuming an ideal behavior of the vapor phase:

$$P_{MEA}^{cal} = y_{MEA}^{cal} * P_t (4$$

In a second step, we compared $P_{\text{MEA}}^{\text{cal}}$ with the experimental P_{MEA} , Figs. (4) and (5) (a). At 313 K, the calculated value is higher by 2 Pa comparing with our value whereas at 333 K, the difference is 10 Pa. Our data are systematically higher. Here again, the difference is acceptable with regard of the low explored pressures. On the other hand (Hilliard, 2008) data at 333 K ($\alpha=0$) is lower comparing to (Belabbaci et al., 2009) value.

As for the partial pressures of water, no variation is observed in

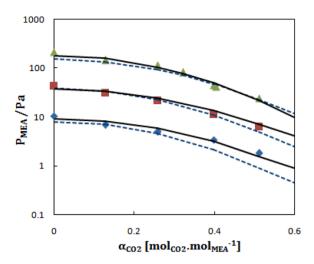

Fig. 11. Partial pressure of MEA in $(H_2O\text{-MEA-CO}_2)$ mixtures, 30 wt% MEA. Experimental points:313 K; 333 K; 353 K. Solid lines: (Xu, 2011) empirical model, Eq. (5), fitted on our experimental points; dashed lines: calculated data using the parameters obtained by Xu (2011).

function of α : water concentration in the liquid is stable with the addition of CO_2 because there is no reaction with water in the studied range ($\alpha \leq 0.5$), Fig. 6. Water only plays a role during the hydrolysis of carbamates which takes place when $\alpha > 0.5$. The data are in very good agreement with those of (Hilliard, 2008) at both temperatures (313 and 333 K), Fig. 6.

Fig. 7 (a–c) shows the comparison of $P_{\rm CO2}$ data with those of literature (Aronu et al., 2011; Hilliard, 2008; Jou et al., 1995; Shen and Li, 1992) at 313, 333 and 353 K. A very good agreement is observed with the different authors.

3.4. Vapor-liquid equilibria of water + TMEDA + CO $_2$

TMEDA is a compound with two tertiary amine functions. The system (water+TMEDA+CO₂) was studied at 10, 30 and 50 wt%, Tables 6–8. In Fig. 8 (a–c) are plotted the partial pressures of the amine function of the loading of CO₂. We observe a decrease of P_{TMEDA} when α increases. In addition a maximum seems to be emerging for 30 wt% TMDEA and clearly observed at 50 wt% TMEDA.

The gradual appearance of the maximum could be explained by the existence of two "antagonistic" contributions when α increases. First, the decrease of P_{TMEDA} is due to the chemical reaction between the amine and CO_2 which decreases the concentration of the amine remaining in solution. Secondly, an increase of P_{TMEDA} is due to a "salt effect" phenomenon because of the increasing quantity of ammonium salt formed. It should be noted that TMEDA is an "aprotic" amine, with a

hydrophobicity characterized by the appearance of a demixing of TMEDA-water mixtures when heating at temperature over 363 K which is the Lower Critical Solution Temperature (LCST), (De Oliveira, 2010). Above this temperature, the thermal energy is sufficient to disrupt the chemical interactions between TMEDA and water and cause demixing.

The partial pressure of water function of α is almost constant, Fig. 9, whereas the partial pressures of CO_2 increase with CO_2 loading. Comparing to the MEA solutions, the curves have not the same shape: no inflection at $\alpha=0.5$ is observed. In the case of MEA, this inflection indicates that the absorption of CO_2 is changing from a chemical mode (chemical reaction between amine and CO2) to a physical absorption for $\alpha>0.5$ (steeper slope).

TMEDA is a diamine, the inflection point must be around $\alpha = 1$. We have not explored the $(\alpha > 1)$ range and therefore the physical absorption does not appear in Fig. 10 (a–c).

No literature data for comparison was found for these mixtures.

3.5. Correlation of amines partial pressure

For the correlation of MEA volatility, (Xu, 2011) developed an empirical expression which is function of the partial pressure of the primary amine, the initial mole fraction of the amine in the liquid phase (x_{MEA}), the equilibrium temperature and the CO₂ loading (α), Eq. (5):

Table 9 pKa of the two amine functions of TMEDA and PZ (El-Hadri, 2012).

	pKa ₁	pKa ₂
TMEDA	8.9	5.6
PZ	9.73	5.35

Table 10
Regressed parameters of Eq. (5)*.

	A	В	С
Xu (2011)	30.0	-8153	-2594
This work	27,8	-7317	-2100

$$*ln\left(\frac{P_{MEA}}{x_{MEA}}\right) = A + \frac{B}{T} + C * \frac{\alpha^2}{T}$$

Table 11
Regressed parameters of Eq. (6)*.

	A	В	С	D
$10 \text{ wt\%TMEDA} + \text{H}_2\text{O}$ $30 \text{ wt\%TMEDA} + \text{H}_2\text{O}$	-177.30 -106.70	32.35 20.17	-2.39 -0.90	-0.88 -0.88
$50 \text{ wt}\%\text{TMEDA} + \text{H}_2\text{O}$	-143.60	26.54	-1.33	-0.88

$$*\ln\left(\frac{P_{TMEDA}}{x_{TMEDA}}\right) = A + B * \ln T + C * \alpha + D * \frac{\alpha^2}{T}$$

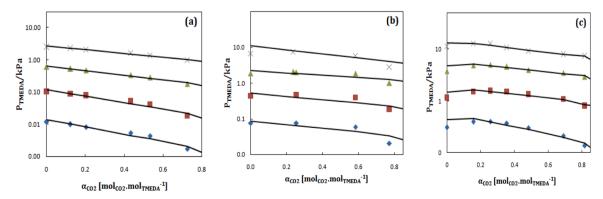

Fig. 12. Partial pressure of TMEDA in (H₂O-MEA-CO₂) mixtures:(a), 10 wt% TMEDA; (b), 30 wt% TMEDA;(c), 50 wt% TMEDA. Experimental points:293 K; 313 K, 333 K; ×, 353 K. Solid lines: empirical model, Eq. (6), fitted on our experimental points.

$$ln\left(\frac{P_{MEA}}{x_{MFA}}\right) = A + \frac{B}{T} + C * \frac{\alpha^2}{T}$$
 (5)

In the same way (Xu, 2011) developed a second empirical equation for diamine (with 2 amine functions) namely for Piperazine (PZ) which is a secondary diamine, Eq. (6):

$$\ln\left(\frac{P_{PZ}}{x_{PZ}}\right) = A + B * \ln T + C * \alpha + D * \frac{\alpha^2}{T}$$
(6)

In a first step we fitted the experimental data of P_{MEA} function α , using Eq. (5) and then compared with the values calculated from (Xu, 2011) parameters, Fig. 11. For the isotherms at 333 and 353 K, a good agreement is obtained, however at 313 K differences appear at higher CO_2 loading (α above 0.2). This result is expected as (Xu, 2011) signaled in his paper that the regression model has a lack of consistency and for that reason excluded (Hilliard, 2008) data at 313 K from the empirical regression model.

Partial pressures of TMEDA were fitted using Eq. (6). The empirical model developed for piperazine, PZ, represents well the partial of TMEDA function α due certainly of the similarity of the chemical properties of these two amines, Fig. 12. PZ and TMEDA are two diamines with very similar acid-base characteristics, Table 9. The parameters of Eqs. (5) and (6) are reported in Tables 10 and 11.

4. Conclusion

Vapor-liquid equilibria of binary systems were studied using an apparatus with on-line analysis by GC of the vapor phase: (water + MEA) and (water + TMEDA) at different temperatures (from 293 to 353 K) and different weight percent of amine (10%, 30%, 40% and 50%) depending of the amine. The partial pressures, P_{MEA} or $P_{\text{TMEDA}},\,P_{\text{H2O}}$ were determined using gas chromatography. A good agreement of the total pressure of the solution, P_{t} , with literature data is obtained. As for the partial pressures, P_{MEA} or $P_{\text{TMEDA}},\,P_{\text{H2O}}$, no data was found for comparison.

In a second step, the systems (water+MEA+CO₂) and (water+TMEDA+CO₂) were studied at several temperatures, different weight percent of amine and various loading of CO₂. In the same way the partial pressures, P_{MEA} or P_{TMEDA} , P_{H2O} along with P_{CO2} were determined.

The explored partial pressures range from 2 Pa to approximately 400 kPa, which is broad. Partial pressures of the system (water+MEA+CO $_2$) are in a good agreement with literature data. As for the mixtures (water+TMEDA+CO $_2$), no literature data was found for comparison. The empirical expressions developed by (Xu, 2011) satisfactorily correlate the partial pressure
